Food Volume & Calorie Estimation

?

How much food is on the plate?

?

How many grams?

?

How many calories?

Estimate food amount and calories from plate images

Volume | Grams | Kcal estimation

Reliable estimation depends on image perspective and available visual information.

Top Image

Visible: food area on the plate — shape and footprint of each item.

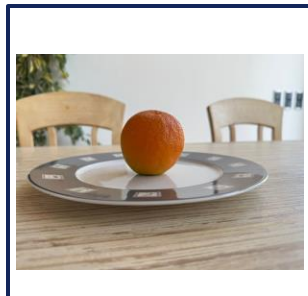

Side Image

Visible: food height and profile — key input for real 3D volume.

Without a side image: no reliable real volume — only a grams-based fallback is possible.

Top + Side

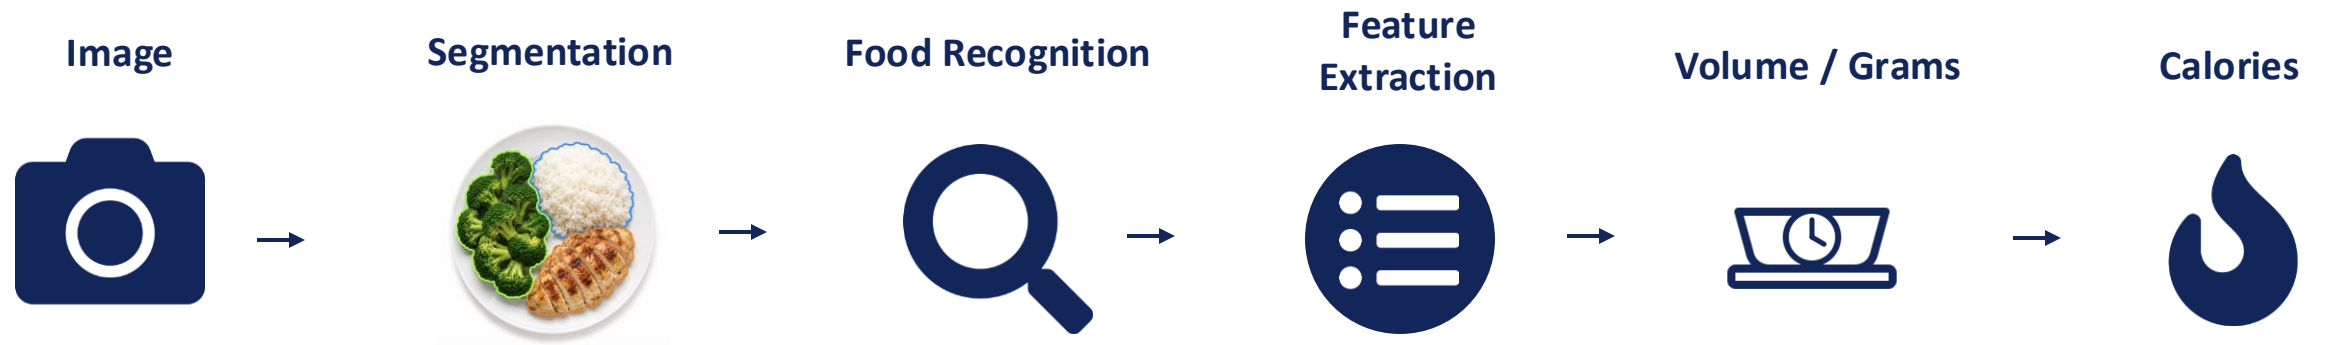

Real volume estimation (ml)

Only Top

Grams fallback — no real volume

Images are transformed into model-ready features before estimation.

Pipeline Components

FastSAM

Segments individual food items on the plate.

CLIP

Recognizes / filters food classes by semantic similarity.

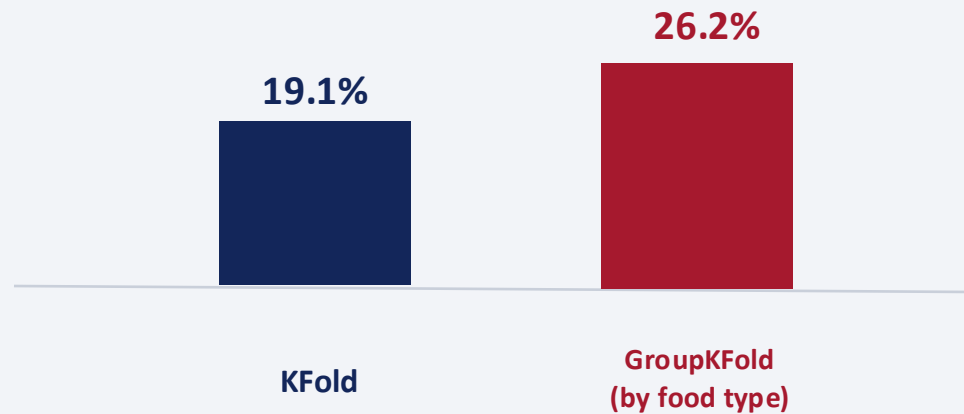

Gradient Boosting Regressor

Volume fallback using area_cm2, height_cm, area_x_height.

The model works, but performance depends strongly on image quality and viewpoint.

Evaluation

MAPE by validation strategy

Limitations

Photo quality

Segmentation errors

Scale estimation

No reliable volume without side image
